

Biomarkers at the Interface of Delirium and Dementia

Presenter: Tamara Fong, MD, PhD

Time	Section
01:46	<p><u>Overview</u></p> <ul style="list-style-type: none"> • This webinar will explore mechanisms that might be common to both delirium and dementia • An overview of shared biomarkers <ul style="list-style-type: none"> ○ AD biomarkers ○ Neural injury biomarkers ○ Neuroinflammatory biomarkers ○ Neuroimaging biomarkers • Future directions
02:17	<p><u>Relationship between Delirium and Dementia</u></p> <ul style="list-style-type: none"> • Figure indicating the interrelationship between delirium and dementia
02:57	<p><u>Delirium and Dementia: Neuropathological Biomarkers</u></p> <ul style="list-style-type: none"> • Delirium is a risk factor for dementia • Delirium not mediated by classic neuropathology • Higher levels of pathological burden with delirium had steeper slopes for decline in cognitive function
06:00	<p><u>Delirium and Dementia: Fluid Biomarkers</u></p> <ul style="list-style-type: none"> • Fluid biomarkers of AD: amyloid, tau, neuroinflammation, neuronal damage, other reactional, and cytokines-chemokines • Amyloid Tau Neurodegeneration (ATN) framework • AD biomarkers change over time (graph) • Plasma p-tau greater in patients with delirium and correlated with delirium severity • Only tau predicted recovery from delirium • All biomarkers increased postoperatively • Biomarker negative and no delirium had lowest delirium severity scores • Biomarker negative and delirium & biomarker positive and no delirium had intermediate delirium severity scores • Biomarker positive and delirium had highest delirium severity scores
15:12	<p><u>Neuroinflammation and microglial activation</u></p> <ul style="list-style-type: none"> • Left figure shows normal functioning • Right figure shows pathological conditions • Delirium associated with higher level of CSF sTREM2 only among those without pre-existing dementias
18:35	<p><u>Neural Injury</u></p> <ul style="list-style-type: none"> • NFL (left figure) & GFAP (right figure) • Delirious patients had significantly higher difference in NFL levels than non-delirious patients • Delirium associated with exaggerated increases in NFL and neurotoxicity can contribute to the delirium itself, but is independent from inflammation • More involvement with GFAP in patients who develop postoperative delirium • Emergence delirium may be more associated with more significant axonal injury •
28:07	<p><u>Summary of Fluid Biomarker Evidence</u></p> <ul style="list-style-type: none"> • Neuroinflammation <ul style="list-style-type: none"> ○ Associated with both dementia and delirium, separately ○ The influence of neuroinflammation on delirium in the presence of dementia pathology seems to be variable • AD

	<ul style="list-style-type: none"> ○ Most but not all studies support an association between the presence of AD biomarkers and delirium incidence ○ Gene-protein interactions may modify other processes (i.e. neuroinflammation) to promote delirium ● Neural injury markers <ul style="list-style-type: none"> ○ Neuronal, astrocytic and glial biomarkers are mixed <ul style="list-style-type: none"> ▪ Delirium itself might promote additional injury and further release of injury markers ▪ Multiple injury pathways (via AD, neuroinflammation, etc. may be involved in the relationship between delirium and dementia)
29:32	<p><u>Delirium and Dementia: Neuroimaging Biomarkers</u></p> <ul style="list-style-type: none"> ● Neuroanatomic basis for delirium symptoms <ul style="list-style-type: none"> ○ Right parahippocampal region and right parietal lobe are associated with acute delirium symptoms ● Brain Volume and Cerebral Atrophy <ul style="list-style-type: none"> ○ Variable findings in association of brain volume and cerebral atrophy and delirium include natural individual variations in brain volumes and differences in measurement techniques ● Reduced Grey Matter Volume is a Risk for Delirium <ul style="list-style-type: none"> ○ Grey matter volume (as a fraction of total volume) can predict delirium ○ In the surgery group, delirium associated with greater decrease in grey matter volume ● White Matter Hyperintensities <ul style="list-style-type: none"> ○ The findings from other studies of white matter hyperintensities and delirium are mixed, possibly due to differences in methodology. Most studies are in post-surgical populations, and the findings may not be generalizable ● Diffusion Tensor Imaging <ul style="list-style-type: none"> ○ Alterations in the microstructure of the white matter may increase risk for delirium ● Delirium Duration is Associated with White Matter Disruption <ul style="list-style-type: none"> ○ Compromised white matter integrity in areas of the brain involved in interhemispheric connectivity are associated with delirium ● Diffusion Tensor Imaging Identifies Neural Substrates of Vulnerability to Delirium <ul style="list-style-type: none"> ○ Structural dysconnectivity and microstructural tissue changes can predispose to delirium under the stress of surgery ● MRI Brain Phenotypes Might Predict Delirium ● Changes in Cerebral Perfusion <ul style="list-style-type: none"> ○ Measurements from TCD support reduced blood flow to be associated with delirium ○ No association between global and voxel-wise CBF and POD incidence or severity ● Cerebral Hypometabolism <ul style="list-style-type: none"> ○ Supports hypothesis that delirium results from cerebral metabolic insufficiency ● Regional Hypometabolism in Delirium is Independent of Illness and Dementia <ul style="list-style-type: none"> ○ Regional hypometabolism correlated with increased delirium severity and decreased performance on neuropsychological testing ● Association of Postoperative Delirium with Markers of Neurodegeneration and Brain Amyloidosis <ul style="list-style-type: none"> ○ Brain amyloidosis is unlikely to be a major cause of poor brain resiliency increasing the risk of POD after nonelective surgery ○ Recall that delirium pathophysiology might be independent of Alzheimer’s disease
50:09	<p><u>Summary of Neuroimaging Findings</u></p> <ul style="list-style-type: none"> ● Pre-existing brain damage (cerebral atrophy, ischemic lesions, and white matter lesions) is a strong predictor of delirium ● Changes in perfusion and metabolic activity may reflect microscopic tissue damage and glial activity
50:45	<p><u>Research Challenges</u></p>

	<ul style="list-style-type: none"> • As delirium results from the interaction between predisposing vulnerabilities and precipitating insults, patient selection may influence imaging outcomes
52:15	<p><u>Research Priorities</u></p> <ul style="list-style-type: none"> • Better matching of patient demographics could help strengthen findings • Studies examining changes over time may demonstrate stronger relationships than cross-sectional studies • Longitudinal studies may help define transient effects of delirium from pre-existing vulnerabilities (i.e. dementia), and enables investigation of long-term brain changes associated with delirium • Larger sample sizes would help confirm findings • Studies involving vulnerable patients such as those with acute illness and dementia would be more representative of the clinical population most affected by delirium
53:34	<p><u>Questions and Answers</u></p>
